Stakeholders' influence on environmental sustainability of reusing religious heritage in the UK: A case of historic churches

Author's Details:

Akande, Oluwafemi Kehinde

Department of Engineering and the Built Environment, Anglia Ruskin University, Chelmsford, United Kingdom

Abstract:

Current global pressures on energy consumption have elevated the objective of energy efficiency both within the scientific and legislative agenda. This is due to increasing scarcity of natural resources and impacts on climate change originating from traditional fossil fuel-based energy generation. However, as the momentum gathers for improving environmental sustainability of buildings, it is inevitable that no aspect of building sector could be left a_b in meeting the carbon emission reduction target for the building sector. An aspect identified for potential reduction energy use is religious heritage; especially those currently undergoing reuse for other public uses. Presently, little; achieved with regards to reducing environmental impacts of reusing these buildings. The paper aims is to investigate influence of heritage building stakeholders on strategies to improve environmental sustainability of reusing histori churches. The objective is geared towards improved process and approach for their sustainable reuse. Using questionnaire survey, this study engaged heritage professionals involved in the refurbishment of religious heritage across the UK. Findings shows that environmental impacts of reusing historic churches have not yet been factore into these projects and that heritage building professionals' influence and perception is vital to reducin environmental impact of these buildings. Further findings suggests other material issues for improved process and/h decision involving reuse of these buildings should include holistic sustainability objectives and agenda for effective energy use management. The paper conclude greater emphasis on energy management and waste reduction would need to be integrated into the strategic and business planning for sustainable reuse of these buildings.

Keywords: environmental sustainability, religious heritage, stakeholders, influence

1. Introduction

The significance of the building sector has necessitated the agreement of the key world peerreview assessments, such as the Fourth Assessment Report of the Intergovernmental Panel on Climate Change [1], the Global Energy Assessment [2], Energy Technology Perspectives [3] and others on buildings as a priority sector when considering energy security and climate mitigation challenges. Considering its overall significance of climate change, a considerable importance is attached to incorporating energy saving measures to new buildings and concentrated efforts to improving energy efficiency of existing buildings.

Arguably, older buildings especially those with heritage value also have a crucial role in meeting the targets for moving to a low-carbon future. English Heritage [4] and Rowe et al., [5] expressed concern over the replacement of existing building for a new arguing that it would require a considerable investment of 'embodied' energy in materials, transport and construction. In Europe, there are about 500,000 existing religious heritage buildings with a history dating back well over a 1000 years representing a unique and essential part of Europe's cultural heritage with key element of European identity [6].

The religious heritage buildings have stood central

to their communities for hundreds of years and ha continue to play integral and crucial part for the future survival of their communities. Thus, the importance of religious heritage has been recognise for both cultural and heritage conservation for the community's current and future life. However, du to inevitable change in human society such increasing trend of secularization leading to ongoin redundancy of many religious heritage building especially churches; lots of them are coming und threat and therefore have become open for not religious activities.

In the past, buildings that were structurally secur have been adapted to fit changed needs of society or new functions. This process of change function of a building though not always result changes to the structure or the interior is temp adaptive reuse. Velthuis and Spennemann [7] argue that this process of change requires a certain amou of creativeness and inventiveness, not just from architects involved in finding a way to fit a no function for the old building, but all those involve in the process.

During the French Revolution, religious building were transformed into industrial functions military uses after they had been confiscated sold [8] - [9]. Although, these interventions we done in a pragmatic way, however, the driving force behind them was only functional and financial [10]. Meanwhile environmental sustainability aspect of reuse of these buildings is not viewed as a strategic issue and currently still under-researched in the literature most especially reuse of historic churches.

1.1 Adaptive reuse of historic churches

A factor driving adaptive reuse of churches especially those with heritage value is redundancy. According to English Heritage [11] redundant buildings are buildings that have reached the end of their original working lives but often have huge potential to be adapted to economically viable new uses. In the UK, majority of heritage buildings affected by redundancy are places of worship converted to alternative use or demolished. Rauti [12] expressed that generally, all denominations have been affected by the increase of the rate of redundancy.

In the UK, there are approximately 45,000 churches with Church of England (CoE) alone having about 16,200 churches of which more than 12,200 are heritage listed with some 52% being listed as either Grade I or Grade II* [13]. Whilst most the churches remain in use for worship, however, some 1,626 have been declared redundant between 1969 and 2004; a trend predicted to continue at a rate of 30 buildings per year [14]. Thus, the adaptive reuse of church buildings becomes significant in conservation fostered by the economic benefits associated with tourism they could generate [15] – [17].

Velthuis and Spennemann [7] observed that demolition affects about one fifth of the redundant churches predicting that about 60% of all redundant churches could end up in demolition. In addition, to challenges of reuse of historic churches, some are observed to be ill adapted to meet the needs of modern society. However, to effectively safeguard and reduce the vulnerability of these important heritage assets to be lost, improving their environmental sustainability in an innovative way would be needed not just at the European level but also at various national level if their remarkable patrimony is to be handed to future generations.

2. The case for environmental sustainability in adaptive reuse of historic churches

Rising energy costs with its associated environmental impact has driven the quest for

development of new ideas and solutions to achieve sustainable adaptation of heritage buildings. Ellison et al. [18] asserted that the rising trend in energy prices will drive property investors to improve the energy efficiency of buildings so as to sustain market demand and rental growth. Therefore, greater attention is directed to updating existing buildings to improving their environmental sustainability standard and to potentially making them more economical to operate; thus giving them longer life span.

Cooper [19] specifically posited that upgrading the performance of existing buildings stock (i.e. adaption) is the most critical aspect of improving sustainability of the built environment. Steemers [20] however argued that for a building to be truly sustaining, it needs to endure and adapt to climate change incrementally over time. Douglas [21] in line with this view drew attention to adaption has an opportunity to implement sustainability into buildings thus making its environmental argument strong.

Brown [22] and Bruhns et al., [23] extended these views stating that operational energy in non-domestic buildings has risen drastically within the last four decades and such necessitated energy improvements in re-using existing buildings. This has the potential to provide substantial cost savings for owners and occupiers. While the case for environmental sustainability and the numerous potential benefits of reusing heritage buildings for other purposes has been acknowledged and highlighted, however, current approaches have only tended to give more recognition to the significance of these buildings as community cultural identity [24] – [25].

Meanwhile available sources omit the influence, practices and perception of heritage building stakeholders neither seek to develop theory nor any framework for practice. For instance, conservation professionals' focus and decisions appear to be principally based on their perception of conserving the features and the identity of the buildings. Meanwhile, little is mentioned with regard to the implications of the energy use in adaptive reuse of these buildings. Most striking is the lack of attention given to influences from project stakeholders.

English Heritage [26] while responding to the challenges of climate change recommends that sustainability appraisal of historic building stock should put into consideration the whole-life energy costs allowing for strategies to increase its sustainability in terms of energy and materials in

mitigating climate change effects. Arguably, when historic churches are converted to another use, the indoor temperature, the level of comfort required for the users and energy consumption of the building would change. This would require some degree of caution and care by the design professionals as ill-designed interior space and systems can result to adverse effects on the users and the fabric of the building [27]. This could lead to draughts, thermal stratification, condensation, and deterioration of historic artefacts and possible elevated energy consumption [28]. This underscores the need to adapt and retrofit them to optimal energy performance standard for their new operation.

Currently, the Church of England (CoE) emits about 330,656 tonnes of CO₂ in its operations, yearly [29]. According to Figure 1, the major source of energy consumption of the churches are shown to be mainly due to heating (36%) and lighting (31%). Although limited scope of their energy refurbishment options exists due of their historic value, however, savings of up to 25% are assumed could be achievable through routine energy saving strategies and utilising energy efficient equipment [29. However, conversion of some of these churches to other uses could offer great opportunity to achieve part of the aim to achieve 80% reductions of churches' carbon emissions by 2050. This necessitate the need for greater understanding of the potential environmental savings that can be achieved by reusing these religious heritage.

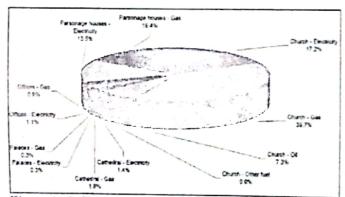

Figure 1: CoE's CO₂ emissions by source Source: Church of England [29]

This study investigates the perception and influence of heritage building stakeholders on strategies to improve environmental sustainability of reusing religious heritage with particular reference to reuse of historic church buildings. The objective of the study is twofold:

· To determine the pragmatic impact of the

- influence of the stakeholders on improven environmental sustainability of recent religious heritage buildings;
- To determine the most sustainable compatible approach adopted by differ stakeholders to reuse of religious heritage perceived by the stakeholders.

This research is intended to serve as a resource policymakers, building owners, designers theritage preservation advocacy groups. To this the study identifies key environment considerations and challenges related to retrofits to reuse of religious heritage.

3. Research methodology

Very few if any studies on investigate perception stakeholders' environmen of sustainability of reusing religious heritage exists, the literature. As part of the a doctoral research energy management for sustainable reuse of public heritage buildings; the author developed questionnaire instrument to lay a foundation developing a tool to aid decision making environmental sustainability of reuse of religion heritage buildings. The use of questionnaire surve was considered appropriate to reach a large number of stakeholders concerned and as an objects method to obtain opinions on the issues to investigated.

A similar approach was adopted by Elmualin al. [30] to investigate the perceptions of respondent in other UK's industries. Gaps identified in a literature relating to the perspectives of stakeholds were used to develop an online questionname survey. The survey was piloted, discussed appropriate instrument to collect the required deappropriate instrument to collect the required deappropriate instrument was sent via email to the professionals in the UK's industry within period of two months between May to July 2007. The respondents involved in this study architects, engineers, surveyors, planning architects, engineers, surveyors, planning conservation officers.

The questionnaire contained 19 question however, the aspect consider for this paper of comprises of Part C - the construct of perception and Part E and F in construct of perception on sustainable appropriately. The dimensions of stakeholders' influe and perception (i.e. PEU and PSA) variable measured in the survey were rated on a scale range from 1 to 5 from "Highest" to "Lowest." The sould

http://www.casestudiesjournal.com

indicated the stakeholders' influence and perception on sustainability consideration in the project.

4 Results and findings

A total of 211 responded to the survey. Therefore, the sample size is considered adequate. Cronbach's Alpha value was employed to determine the level of reliability of the internal consistency of each item. The result shows that the stakeholders' perception on PEU dimensions achieved Alpha value level exceeding 0.60 (Alpha = 0.76) indicating a good reliability value. The corrected item-total correlation to all items is found to be greater than 0.3 indicating the degree at which each item correlates with the total score [31]. There are 29.8% (63) architects, 30% (64) conservation officers, 9.5% (20) energy consultants, 13% (28) engineers, 8% (16) planning and development control officers, 4.7% (10) regulatory officers and 4% (8) surveyors and 1% (2) others who participated in this study.

4.1 Consideration of energy use reduction for church conversion projects

Table 6.13 present the respondents rating on sustainable considerations for church conversion projects. The overall ranking, in ascending order is: conservation policies; users comfort; low energy operating cost; and low energy installation cost. The results show that conservation policies are consistently held in high consideration by the respondents in every project. Meanwhile, low energy consideration trails in the third and the least considered in the projects. The ranking of conservation policy as the most important is not unexpected as policymaker's greatest obligation for any heritage building project is to ensure compliance with conservation policies.

Table 1: Energy use reduction as sustainable consideration factor and ranking

	Free	quency	nts' i	s' ranking of the factors				
Considerations for Church conversion	1	2	3	4	5	SD	Mean	Rank
Low energy installation costs	16	37	42	21	7	1.074	2.724	4
Low energy operational cost	16	18	42	37	10	1.140	3.057	3
Users comfort/productivity	6	13	43	46	15	0.999	3.415	2
Strict compliance to conservation Policies	0_	5	25	40	52	0.884	4.139	1_

The Spearman's Rank Correlation Coefficient test performed on respondents' sustainable consideration factor for church conversion projects yielded the following results: Conservation policies (R-value = 0.218, $\rho = 0.016$); Users' comfort (R-value = -0.422, $\rho = < 0.01$); Low energy operating cost (R value = -0.472, $\rho = < 0.01$); Low energy installation cost (Rvalue = -0.39, ρ = < 0.01). This indicates that there is significant difference between the policy makers and the professionals in their perception (Table 2). To investigate the influence of the respondents' PEU as it impact their strategies adopted in practice for energy use reduction; binary logistic regression analysis was used to determine the ability to predict the adoption of a given strategies adopted by the respondents as indicated in the survey. A dummycoded 0 was adopted for non-adoption of a strategy

while I was dummy-coded for adoption of a strategy. In terms of adopting improvements of the building fabric to reduce U-value, it can be seen from Table 3 that the Wald statistic obtained in the test was 12.04 at the significance value of 0.001. It can be seen that the value fails to attain the 0.05 threshold. Since the value fails to attain the 0.05 threshold it can be concluded from the finding that respondent's choice of adopting the improvement of the building fabric to reduce U-value, is influenced by their perception. However, to confirm this, the -2 log likelihood value is presented as 255.468 in Table 3. This is fairly high and in accordance with the recommendations of Fields [32] caution needs to be taken in concluding that the model might not be good in the prediction of this strategy from the respondents' perception.

Table 2: Spearman's rank Correlation Coefficient test result on energy use reduction for projects

Table 2. Spearman	N	Spearman Correlation	ns	
Considerations for Church conversion	Professionals	Policymakers	R-value	Sig (p)
	3.088	2.273	-0.39	< 0.01
Low energy installation costs	•	2.473	-0.472	< 0.01
Low energy operational cost	3.529	2.473		< 0.01
Users comfort/productivity	3.809	2.927	-0.422	<0.01
Strict compliance to conservation				0.016
Policies	3.985	4.327	0.218	0.016

In order to represent the overall model fit, the Cox and Snell R² and the Nagelkerke R² values categorized as pseudo R² are indicated in Table 3. The Cox and Snell R² and the Nagelkerke R² values are interpreted to reflect the amount of variation accounted for by the logistic regression model, with

1.0 indicating perfect model fit [33]. According to Table 3, the Nagelkerke R² value is 0.084, meaning that a significant relationship of 8.4% can be found between the respondents' perception and the adoption of improving building fabric to reduce to value as a strategy for energy use reduction

Table 3: Influence of stakeholders on strategies for energy use reduction in the projects

and awareness)	245240	.043	.059	Constant	-2.020	524	14.884	1	.000	13	

In addition, it can be seen from Table 3 that the odds ratio as expressed by Exp (B) = 1.029 and since it surpasses the threshold of 1.00; it can be deduced that any increase in the respondents' PEU will increase the odds of adoption of improving building fabric to reduce U-value. This interpretation also goes for the choice of other strategies such as building services upgrade, smart metering and operational energy management policy and

awareness. For other strategies such as end management system, smart lighting control renewable installations, it can be seen from the that the significance value of the Wald state obtained was greater than 0.05. Since the surpasses the 0.05 threshold, it is notable from results that respondents' choice of adopting the strategies was not influenced by their perception could be observed that the -2 log likelihood to

vere also very high and in accordance with the ecommendations of Fields [32], it can be concluded hat the model would not be sufficient to predict the trategies adopted from the respondents' perception.

Furthermore, it could be seen that the Vagelkerke R² value were also low, meaning that here were very mild or no relationship between the respondents' perception and their adoption of the stated strategies energy use for reduction. However, the odds ratios as expressed by Exp (B), were all greater than 1.00. Since the odds ratio surpasses the threshold of 1.00, it can be concluded that any increase in the respondents' PEU will increase the odds of adoption of the stated strategies for energy use reduction. To determine the source of the difference in the respondents' PEU reduction, the respondents' scores were subjected to One Way Analysis of Variance (ANOVA). The differentialing variables used includes the following: respondents: status such as profession and/or role in heritage industry, geographical location, years of working experience on heritage building projects and the number of heritage refurbishment projects they have been directly involved. The result on the test of difference on the basis of the respondents' profession and/or role in the heritage industry is presented in Table 4. The F-ratio in the results is used to determine the statistical significance. The result show the F-value obtained to be 2.740 at a pvalue of 0.010. Since the ρ-value is less than 0.05, it can therefore be concluded that the respondents differs in their PEU reduction on the basis of their profession and/or role in heritage industry.

Table 4: Test of difference in the perception of the stakeholders based on their profession

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	6008.071	7	858.296	2.740	.010
Within Groups	59209.574	189	313.278		
Total	65217.645	196			

Similar test carried out for other differentiating variables yielded the following result: location (F-value = 1.822, p-value = 0.059); years of working experience (F-value = 0.342, p-value = 0.887) and number of heritage building refurbishment projects (F-value = 1.740, p-value = 0.127). It could be observed that p -value is greater than 0.05 for other differentiating variables; therefore be concluded that the respondents do not differ in their PEU reduction in on the basis of the other variables. Meanwhile, since the F-value is significant for the respondents' professional status, the source of the significance difference was investigated through a post-hoc multiple comparison tests conducted via Tukey HSD (Honestly Significant Difference). The results as

presented in Table 5 show that there is a mean difference in the group professional status. The result of the mean difference (MD) indicate that engineers seem to have the best perception and gives higher priority and values to environmental sustainability to the projects among the respondents. Their perception was significantly better than those of the energy consultants (MD = 16.74) and conservation officers (MD = 15.38). Although, conservation officers were also found to possess a good (MD = 1.37), the difference was not found to be significant. Further findings shows that other stakeholders were not found to be significantly different in their perception regarding environmental churches. historic reusing sustainability of

4.2 Stakeholders' perception on environmental sustainability construct

To validate the construct on PSA exploratory factor analysis (EFA) using SPSS software was carried out on items on section B and D in the survey. This allows for the exploration of factors perceived by the respondents for sustainable approach to reducing environmental impacts in reusing historic churches. Starting with the original data matrix and using multiple correlations as the estimates of communalities, principal factors were

extracted after interacting of communalities. Factors with eigenvalue greater than 1 were retained for rotation. The procedure yielded two factors seven factors components. The factors were extracted and identified using the features of the items loaded and labelled according to their groupings as follows: Energy management (1); Design decision (2); Government regulations (3); Limited resources and

grants (4); Risks of condensation and building complexity (5); Heritage visual impact secondary glazing (6) and Fabric U-value (7). The labelled factors indicate the critical factors to be addressed to achieve energy use reduction for sustainable reuse of PHBs (Table 6).

5. Discussion

han Lincovariate is turbed to the

The stakeholders influence and perception on environmental sustainability of reusing religious heritage have been examined through the study. It can be said that the respondents differs in their PEU especially on the basis of their profession. The professionsis among the respondents have better perception than the policymakers. This difference could perhaps be possibly due to the perception among the policymakers that there is little room for improving the environmental sustainability of historic churches. Partly, because of the way historic charches are built hundreds of years ago and more

importantly because of the impulse to protect \$\(\bar{p}_A \) delicate fabric which pose limitations to com 'easy wins' of energy efficiency. It implies that'n policymakers would need to develop more prosti inclination to incorporating environmental messe to buildings that are more likely to be adapted so understand what the potential is for those builde for environmental upgrading. It is notable that so professionals are influenced by their perception adopt strategies to improve the building fabril reducing the U-value of the buildings. Post explanations as to why some professionals are professionals. to adopt this strategies could be that they percent it as the most sustainable way of improving environmental sustainability of the buildings compelling explanations could be that this street give greater comfort during the winter season poorly insulated walls in humid buildings in period are likely to show signs of mold at cold (thermal bridges). In addition, adding insula could be part of the overall strategy to reduce at

infiltration that are common to historic churches. However, the potential and effectiveness of adopting this strategy cannot be predicted as a sustainable approach for historic churches as the outcome of the model is not sufficient to base the prediction. Meanwhile others who do not adopt the strategy might perhaps perceived the strategy to be more intrinsically risky for the buildings because of their heritage value. This findings is in line with the reports of other researchers [34] – [37] who pointed out that motivation or adoption of strategies to reduce energy consumption in buildings will vary with the individual inclinations or perception.

On the other hand it can be said that increase in the respondents' PEU could result to the consideration of other strategies such as building services upgrade, smart metering, operational energy management policy and awareness becoming higher priority over fabric improvement. Further findings improving from this that study suggest environmental sustainability of historic churches could be achieved with improved process and/or appropriate decision that include holistic sustainability objectives and agenda for effective energy use management. Other material issues to be considered include making financial resources and grants available, avoiding measures with potential risks of condensation and adequate consideration for the visual impact the measures could have on the building. Strategies such as energy management system, smart lighting control and renewable installations are also potential measures for consideration to make reuse of historic churches sustainable. There is need for the stakeholders to place greater priority and values to environmental sustainability of religious heritage buildings first to increase their future value and to contribute positively to the climate change agenda.

6. Conclusions

This study brings to the fore that that one of many reasons for poor energy performance of heritage building projects could partly be attributed to low perception of the need to improve their energy performance at the decision stage and lack of consensus and commitment to environmental sustainability among heritage stakeholders. The study underscores the need for positive change in perception and attitudes, more enlightenment, training, integrated teamwork and collaboration among heritage professionals to successfully deliver environmentally sustainable reuse of historic building projects. It is recommended that when

Page 31

looking to install energy efficient solutions to religious heritage, it is important to focus on the key important factors in order to safeguard the building from unintended consequences. It is recommended that any technological approach to reuse of religious heritage should align with conservation principles and should be: unobtrusive; non-disruptive; and flexible. In addition, maintaining the fabric and integrity of the building are vitally important.
